GenBA-P Applied to the NYC Project

Oct 20, 2026 · @Syed Zulkifal Banuri

What GenBA-P is

GenBA-P is your lecturer's GenAI-enabled Business Analytics Process: CRISP-DM's six phases, with business strategy and KPIs as guardrails around every phase. Each phase adds two things:

- **GenAI assist:** how GenAI can speed up the work (drafting, coding, summarising).
- **Human checkpoint:** what a person must verify, decide and own before moving on.

The lecture frames the human role as four actions: **Direct, Verify, Decide, Own**. The lab manual turns this into a notebook habit of three cells per GenAI task: a Markdown cell for the prompt, a Code cell for the code you ran and tested, and a Markdown cell for what you checked and changed.

How the phases map to your NYC project

CRISP-DM was designed for predictive modelling, but yours is a database project, so "Modelling" becomes data modelling. State this choice in the report and justify it.

Phase	In your NYC project
1. Business Understanding	Strategy, KPIs, problem statement and the 4–6 business questions
2. Data Understanding	Profiling the CSV: missing values, inconsistent labels, units, ambiguous columns
3. Data Preparation	Python cleaning, splitting the benefits column, and the ETL load into MySQL
4. Modelling	The ERM and relational schema (data modelling, not machine learning)
5. Evaluation	Do the SQL queries answer the business questions and meet the phase 1 success criteria? Check numbers against the source.

Phase	In your NYC project
6. Deployment	The MySQL database, the Python connection, how an API would expose it, and a visualisation

What this changes in the plan

1. **Use one JupyterLab notebook as your working record.** Start with a Markdown cell for strategy and KPIs, give each phase its own heading, and use the three-cell pattern wherever you use GenAI. It doubles as evidence for your IT Lab check-ins and replaces the separate design-decision log.
2. **Write the strategy and KPIs cell first (week 1).** For example: aligning NYC's capital spending with climate goals, with KPIs such as the share of planned spending rated aligned and the share still pending a rating.
3. **Be careful what you paste into GenAI tools.** The lab says to share column names and a small synthetic sample, not real data. The NYC data is public, so the risk is low, but follow the practice and mention it in the report.
4. **Run the notebook top to bottom** with Kernel > Restart Kernel and Run All Cells before you submit or show it.

What to write in the report

Give GenBA-P roughly 150–200 of your 900 words:

- Describe how you applied it, with one or two concrete examples, such as a prompt that produced pandas cleaning code and what you changed after checking it.
- Say where GenAI helped (coding, drafting profiling scripts) and where it could not be trusted (judging bias, or whether a choice fits the business question).
- Link the limits to the lecture's risks: hallucination, bias, replication and privacy.
- Evaluate GenBA-P itself. Is it a good fit for a database project, and what does it assume? Critique earns more marks than description.
- Cite the lecture as course material, and use **Salazar and Kunc (2025)**, The contribution of GenAI to business analytics, Journal of Business Analytics 8(2), pp. 79–92, as one of your 10–15 references.

Ask your tutor how to cite GenBA-P in Harvard style, since it may not exist in published form.
